- Confidence Intervals
- Hypothesis Testing
- Regression and Correlation Formulas

Descriptive Statistics Formulas

Descriptive statistics form the foundation for summarizing and describing the main features of a data set. The formula sheet for AP Statistics includes key formulas that measure central tendency and variability.

Measures of Central Tendency

Central tendency describes the center point or typical value of a data set. The most common measures are the mean and median.

- **Mean ($\bar{x}$):** The average of all data points, calculated as the sum of observations divided by the number of observations.

- **Median:** The middle value when data is ordered from least to greatest, useful for skewed distributions.

Measures of Variability

Variability indicates how spread out the data points are around the center. Key formulas include variance and standard deviation.

- **Variance (s^2):** The average of squared deviations from the mean, measuring data spread.
- **Standard Deviation (s):** The square root of variance, representing average distance from the mean in original units.
- **Interquartile Range (IQR):** The difference between the third quartile (Q3) and the first quartile (Q1), measuring spread of the middle 50% of data.

Probability and Counting Rules

Probability formulas on the formula sheet help quantify the likelihood of events occurring. Counting rules assist in determining the number of possible outcomes in complex scenarios.

Basic Probability Formulas

Probability is expressed as a value between 0 and 1, representing the chance an event will occur.

- **Probability of an event (P):** $P(A) = \text{Number of favorable outcomes} / \text{Total number of outcomes}$.
- **Complement Rule:** $P(A^c) = 1 - P(A)$, representing the probability that event A does not occur.
- **Addition Rule:** $P(A \text{ or } B) = P(A) + P(B) - P(A \text{ and } B)$, used for the probability of either event occurring.
- **Multiplication Rule:** For independent events, $P(A \text{ and } B) = P(A) \times P(B)$.

Counting Techniques

Counting rules provide methods to calculate the number of ways events can occur, crucial for probability calculations.

- **Factorial (n!):** The product of all positive integers up to n, used to count permutations and combinations.
- **Permutations:** Number of ways to arrange n objects in order, calculated as $n! / (n - k)!$ where k is the number selected.
- **Combinations:** Number of ways to choose k objects from n without regard to order, calculated as $n! / [k!(n - k)!]$.

Random Variables and Probability Distributions

The formula sheet contains essential formulas related to random variables and their probability distributions, allowing for the analysis of expected values and variability.

Expected Value and Variance of a Random Variable

These formulas summarize the long-term average and spread of a random variable's outcomes.

- **Expected Value (μ_X):** $\mu_X = \sum [x * P(x)]$, the weighted average of all possible values x.
- **Variance (σ^2_X):** $\sigma^2_X = \sum [(x - \mu_X)^2 * P(x)]$, measuring the variability of the random variable.
- **Standard Deviation (σ_X):** The square root of the variance, indicating spread in the same units as the variable.

Binomial Distribution Formulas

The binomial distribution applies to scenarios with fixed numbers of independent trials, each with two possible outcomes.

- **Probability of k successes:** $P(X = k) = C(n, k) * p^k * (1 - p)^{(n - k)}$
- **Mean:** $\mu = np$

- **Standard Deviation:** $\sigma = \sqrt{np(1 - p)}$

Geometric Distribution Formulas

The geometric distribution models the number of trials until the first success.

- **Probability of first success on the k-th trial:** $P(X = k) = (1 - p)^{(k - 1)} * p$
- **Mean:** $\mu = 1/p$
- **Standard Deviation:** $\sigma = \sqrt{(1 - p)/p^2}$

Sampling Distributions and Central Limit Theorem

Sampling distribution formulas describe the behavior of sample statistics and are critical for understanding inferential statistics.

Sampling Distribution of the Sample Mean

The distribution of sample means approaches normality as sample size increases, according to the Central Limit Theorem.

- **Mean of the sample mean (μ_x):** Equal to the population mean μ .
- **Standard deviation of the sample mean (σ_x):** $\sigma / \sqrt{n}$, where σ is the population standard deviation and n is sample size.

Central Limit Theorem

This theorem states that the sampling distribution of the sample mean will be approximately normal for large sample sizes, regardless of the population's distribution.

Confidence Intervals

Confidence intervals estimate population parameters using sample statistics and provide a range likely to contain the true value.

Confidence Interval for a Population Mean (σ Known)

When population standard deviation is known, the formula uses the z-distribution.

- $\bar{x} \pm z^* (\sigma / \sqrt{n})$
- Here, z^* is the critical value corresponding to the desired confidence level.

Confidence Interval for a Population Mean (σ Unknown)

When population standard deviation is unknown, the t-distribution is used instead.

- $\bar{x} \pm t^* (s / \sqrt{n})$
- t^* is the critical t-value based on degrees of freedom ($n - 1$).

Confidence Interval for a Population Proportion

This interval estimates the true proportion based on sample data.

- $\hat{p} \pm z^* \sqrt{[\hat{p}(1 - \hat{p}) / n]}$
- $\hat{p}$ is the sample proportion.

Hypothesis Testing

The formula sheet includes formulas for conducting hypothesis tests, which assess claims about population parameters using sample data.

Test Statistic for a Mean (σ Known)

- $z = (\bar{x} - \mu_0) / (\sigma / \sqrt{n})$
- Where μ_0 is the hypothesized population mean.

Test Statistic for a Mean (σ Unknown)

- $t = (\bar{x} - \mu_0) / (s / \sqrt{n})$
- Used when the population standard deviation is unknown.

Test Statistic for a Proportion

- $z = (\hat{p} - p_0) / \sqrt{[p_0(1 - p_0) / n]}$
- Where p_0 is the hypothesized population proportion.

Regression and Correlation Formulas

Regression and correlation formulas on the AP Statistics formula sheet help analyze relationships between two quantitative variables.

Least Squares Regression Line

The regression line predicts values of a response variable based on an explanatory variable.

- **Equation:** $\hat{y} = a + bx$
- **Slope (b):** $b = r (s_y / s_x)$, where r is the correlation coefficient, and s_y and s_x are the standard deviations of y and x , respectively.
- **Intercept (a):** $a = \bar{y} - b \bar{x}$

Correlation Coefficient (r)

Correlation quantifies the strength and direction of a linear relationship between two variables.

- $r = (1 / (n - 1)) \sum ((x_i - \bar{x}) / s_x) ((y_i - \bar{y}) / s_y)$
- Values range from -1 (perfect negative correlation) to +1 (perfect positive correlation).
